## A GAME ON THE UNIVERSE OF SETS

## DENIS I. SAVELIEV

Topic #1: Nonstandard Theories and Models, and Foundations of Nonstandard Methods.

Working in ZF without Regularity, we consider a two persons game on the universe of sets. In this game, the players choose in turn an element of a given set, an element of this element, etc.; a player wins if its adversary cannot make any following move, i.e. if he could choose the empty set. (The game, but not any our result, can be found in [1], where it is considered in NF.) A set is said to be winning if it has a winning strategy for some player. The class W of winning sets admits a natural hierarchy: Let a set be  $2\gamma$ -winning if every its element is  $2\delta + 1$ -winning for some  $\delta < \gamma$  and  $2\gamma + 1$ -winning if some of its elements is  $2\gamma$ -winning. Let  $W_{\nu}$  be the class of  $\nu$ -winning sets. Then  $W = \bigcup_{\nu} W_{\nu}$  and each level  $S_{\nu} = W_{\nu} - \bigcup_{\mu < \nu} W_{\mu}$  is nonempty. Let HW be the class of hereditarily winning sets and  $V_{\infty}$  the class of well-founded sets.

**Theorem 1.** *HW* is an inner model and  $HW \supseteq V_{\infty}$ . Moreover, each of four possible cases:  $V = HW = V_{\infty}, V \neq HW = V_{\infty}, V = HW \neq V_{\infty}$ , and  $V \neq HW \neq V_{\infty}$  is consistent.

**Theorem 2.** Let A be a class of ordinals. The assertion " $S_{\nu}$  contains sets without  $\in$ -minimal elements iff  $\nu \in A$ " is consistent iff either A is empty, or  $A = \{\nu > 1 : \nu \text{ is odd}\}$ , or else  $A = \{\nu > 1 : \nu \text{ is odd or } \nu \ge \mu\}$  for some  $\mu$  of cofinality  $\le \omega$ .

For consistency results, we propose a new method for getting models with nonwell-founded sets (different from the customary method of [2], [3]; see also [4]).

In conclusion, we consider the question how long can this game be in general case. Let Pr be a certain natural probability over the class  $V_{\omega}$  of hereditarily finite well-founded sets.

## Theorem 3.

$$\Pr(S_n \cap V_{\omega}) = \begin{cases} 1/2 & \text{if } n \in \{1,3\}, \text{ and} \\ 0 & \text{otherwise.} \end{cases}$$

Thus for almost all elements of  $S_n \cap V_{\omega}$  the game ends either at 1 or at 3 moves, and so the first player wins almost always. Both last theorems display a difference between odd- and even-winning sets by showing that the latter are more complicated and more rare objects.
